Figure 6.4.1. The incomplete beta function  $I_x(a, b)$  for five different pairs of (a, b). Notice that the pairs (0.5, 5.0) and (5.0, 0.5) are related by reflection symmetry around the diagonal (cf. equation 6.4.3).

# 6.4 Incomplete Beta Function, Student's Distribution, F-Distribution, Cumulative **Binomial Distribution**

The incomplete beta function is defined by

$$I_x(a,b) \equiv \frac{B_x(a,b)}{B(a,b)} \equiv \frac{1}{B(a,b)} \int_0^x t^{a-1} (1-t)^{b-1} dt \qquad (a,b>0) \qquad (6.4.1)$$

It has the limiting values

$$I_0(a,b) = 0$$
  $I_1(a,b) = 1$  (6.4.2)

and the symmetry relation

$$I_x(a,b) = 1 - I_{1-x}(b,a)$$
(6.4.3)

If a and b are both rather greater than one, then  $I_x(a,b)$  rises from "near-zero" to "near-unity" quite sharply at about x = a/(a+b). Figure 6.4.1 plots the function for several pairs (a, b).

The incomplete beta function has a series expansion

$$I_x(a,b) = \frac{x^a(1-x)^b}{aB(a,b)} \left[ 1 + \sum_{n=0}^{\infty} \frac{B(a+1,n+1)}{B(a+b,n+1)} x^{n+1} \right],$$
(6.4.4)

but this does not prove to be very useful in its numerical evaluation. (Note, however, that the beta functions in the coefficients can be evaluated for each value of n with just the previous value and a few multiplies, using equations 6.1.9 and 6.1.3.)

The continued fraction representation proves to be much more useful,

$$I_x(a,b) = \frac{x^a(1-x)^b}{aB(a,b)} \left[\frac{1}{1+\frac{d_1}{1+\frac{d_2}{1+\cdots}}}\right]$$
(6.4.5)

where

$$d_{2m+1} = -\frac{(a+m)(a+b+m)x}{(a+2m)(a+2m+1)}$$

$$d_{2m} = \frac{m(b-m)x}{(a+2m-1)(a+2m)}$$
(6.4.6)

This continued fraction converges rapidly for x < (a + 1)/(a + b + 2), taking in the worst case  $O(\sqrt{\max(a, b)})$  iterations. But for x > (a + 1)/(a + b + 2) we can just use the symmetry relation (6.4.3) to obtain an equivalent computation where the continued fraction will also converge rapidly. Hence we have

```
#include <math.h>
```

```
float betai(float a, float b, float x)
Returns the incomplete beta function I_{\mathbf{X}}(\mathbf{a}, \mathbf{b}).

### Student's Distribution Probability Function

Student's distribution, denoted  $A(t|\nu)$ , is useful in several statistical contexts, notably in the test of whether two observed distributions have the same mean.  $A(t|\nu)$  is the probability, for  $\nu$  degrees of freedom, that a certain statistic t (measuring the observed difference of means) would be smaller than the observed value if the means were in fact the same. (See Chapter 14 for further details.) Two means are significantly different if, e.g.,  $A(t|\nu) > 0.99$ . In other words,  $1 - A(t|\nu)$  is the significance level at which the hypothesis that the means are equal is disproved.

The mathematical definition of the function is

$$A(t|\nu) = \frac{1}{\nu^{1/2} B(\frac{1}{2}, \frac{\nu}{2})} \int_{-t}^{t} \left(1 + \frac{x^2}{\nu}\right)^{-\frac{\nu+1}{2}} dx$$
(6.4.7)

Limiting values are

$$A(0|\nu) = 0 \qquad A(\infty|\nu) = 1 \tag{6.4.8}$$

 $A(t|\nu)$  is related to the incomplete beta function  $I_x(a, b)$  by

$$A(t|\nu) = 1 - I_{\frac{\nu}{\nu+t^2}}\left(\frac{\nu}{2}, \frac{1}{2}\right)$$
(6.4.9)

228

}

So, you can use (6.4.9) and the above routine betai to evaluate the function.

#### F-Distribution Probability Function

This function occurs in the statistical test of whether two observed samples have the same variance. A certain statistic F, essentially the ratio of the observed dispersion of the first sample to that of the second one, is calculated. (For further details, see Chapter 14.) The probability that F would be as *large* as it is if the first sample's underlying distribution actually has *smaller* variance than the second's is denoted  $Q(F|\nu_1, \nu_2)$ , where  $\nu_1$  and  $\nu_2$  are the number of degrees of freedom in the first and second samples, respectively. In other words,  $Q(F|\nu_1, \nu_2)$  is the significance level at which the hypothesis "1 has smaller variance than 2" can be rejected. A small numerical value implies a very significant rejection, in turn implying high confidence in the hypothesis "1 has variance greater or equal to 2."

 $Q(F|\nu_1,\nu_2)$  has the limiting values

$$Q(0|\nu_1,\nu_2) = 1 \qquad Q(\infty|\nu_1,\nu_2) = 0 \tag{6.4.10}$$

Its relation to the incomplete beta function  $I_x(a, b)$  as evaluated by betai above is

$$Q(F|\nu_1,\nu_2) = I_{\frac{\nu_2}{\nu_2 + \nu_1 F}} \left(\frac{\nu_2}{2}, \frac{\nu_1}{2}\right)$$
(6.4.11)

#### Cumulative Binomial Probability Distribution

Suppose an event occurs with probability p per trial. Then the probability P of its occurring k or more times in n trials is termed a *cumulative binomial probability*, and is related to the incomplete beta function  $I_x(a, b)$  as follows:

$$P \equiv \sum_{j=k}^{n} \binom{n}{j} p^{j} (1-p)^{n-j} = I_{p}(k, n-k+1)$$
(6.4.12)

For n larger than a dozen or so, betai is a much better way to evaluate the sum in (6.4.12) than would be the straightforward sum with concurrent computation of the binomial coefficients. (For n smaller than a dozen, either method is acceptable.)

## 6.5 Bessel Functions of Integer Order

This section and the next one present practical algorithms for computing various kinds of Bessel functions of integer order. In  $\S6.7$  we deal with fractional order. In fact, the more complicated routines for fractional order work fine for integer order too. For integer order, however, the routines in this section (and  $\S6.6$ ) are simpler and faster. Their only drawback is that they are limited by the precision of the underlying rational approximations. For full double precision, it is best to work with the routines for fractional order in  $\S6.7$ .

For any real  $\nu$ , the Bessel function  $J_{\nu}(x)$  can be defined by the series representation

$$J_{\nu}(x) = \left(\frac{1}{2}x\right)^{\nu} \sum_{k=0}^{\infty} \frac{(-\frac{1}{4}x^2)^k}{k!\Gamma(\nu+k+1)}$$
(6.5.1)

The series converges for all x, but it is not computationally very useful for  $x \gg 1$ . For  $\nu$  not an integer the Bessel function  $Y_{\nu}(x)$  is given by

$$Y_{\nu}(x) = \frac{J_{\nu}(x)\cos(\nu\pi) - J_{-\nu}(x)}{\sin(\nu\pi)}$$
(6.5.2)

The right-hand side goes to the correct limiting value  $Y_n(x)$  as  $\nu$  goes to some integer n, but this is also not computationally useful.

For arguments  $x < \nu$ , both Bessel functions look qualitatively like simple power laws, with the asymptotic forms for  $0 < x \ll \nu$ 

$$J_{\nu}(x) \sim \frac{1}{\Gamma(\nu+1)} \left(\frac{1}{2}x\right)^{\nu} \qquad \nu \ge 0$$
  
$$Y_0(x) \sim \frac{2}{\pi} \ln(x)$$
(6.5.3)

$$Y_{\nu}(x) \sim -\frac{\Gamma(\nu)}{\pi} \left(\frac{1}{2}x\right)^{-\nu} \qquad \nu > 0$$

For  $x > \nu$ , both Bessel functions look qualitatively like sine or cosine waves whose amplitude decays as  $x^{-1/2}$ . The asymptotic forms for  $x \gg \nu$  are

$$J_{\nu}(x) \sim \sqrt{\frac{2}{\pi x}} \cos\left(x - \frac{1}{2}\nu\pi - \frac{1}{4}\pi\right)$$
  

$$Y_{\nu}(x) \sim \sqrt{\frac{2}{\pi x}} \sin\left(x - \frac{1}{2}\nu\pi - \frac{1}{4}\pi\right)$$
(6.5.4)

In the transition region where  $x\sim\nu,$  the typical amplitudes of the Bessel functions are on the order

$$J_{\nu}(\nu) \sim \frac{2^{1/3}}{3^{2/3}\Gamma(\frac{2}{3})} \frac{1}{\nu^{1/3}} \sim \frac{0.4473}{\nu^{1/3}}$$
  
$$Y_{\nu}(\nu) \sim -\frac{2^{1/3}}{3^{1/6}\Gamma(\frac{2}{3})} \frac{1}{\nu^{1/3}} \sim -\frac{0.7748}{\nu^{1/3}}$$
 (6.5.5)
